The mass of the Galaxy can be determined by measuring the orbital velocities of stars and interstellar matter. The total mass of the Galaxy is about $(2 \times 10^{12}) (M_{\text{Sun}})$. As much as 95% of this mass consists of dark matter that emits no electromagnetic radiation and can be detected only because of the gravitational force it exerts on visible stars and interstellar matter.

At the center of the galaxy we have what is referred to as a black hole. I would describe it as a proton star with similarity to how a stars mechanics work only in the opposite way. Because of the negative polarity protons flow in and are converted to electron. Since cold flow with proton a black hole is super cold and unlike stars there are no gases flowing from planets to burn on the surface so no photons leaving to make it shine.

Roger Penrose showed that black holes are a direct consequence of the general theory of relativity. Reinhard Genzel and Andrea Ghez discovered that an invisible and extremely heavy object governs the stars' orbits at the centre of our galaxy, the Milky Way. A supermassive black hole is the only currently known explanation.
